Vision and Mission of the Department

Department Vision

To be a globally recognised excellence hub in Electronics and Telecommunication Engineering, advancing frontier technologies, fostering innovation and entrepreneurship, and nurturing ethically responsible engineers for societal impact.

Department Mission

1. To impart multidisciplinary, industry-aligned education that builds strong technical foundations, advanced analytical and critical thinking, creativity for innovation, leadership capabilities, and readiness for lifelong learning.
2. To promote cutting-edge research, innovation, and entrepreneurship by strengthening faculty expertise through continuous professional development and by fostering collaboration with industry, government, global institutions, and incubation ecosystems to enable students to translate ideas into impactful technologies.
3. To nurture ethical values, professional integrity, social responsibility, and sustainability awareness for developing inclusive, environmentally responsible, and socially impactful engineering solutions.
4. To facilitate global exposure through international collaborations, advanced learning pathways, and engagement with emerging technologies, aligned with national missions, preparing students for global careers, higher studies, and impactful societal contributions.

Foreword

My Students, My Reflection

I am quite fortunate to have chosen a noble career like teaching. According to the scriptures, this is a great compliment for me. In one of the Sanskrit hymns, the teacher has been compared with Brahma, Vishnu and Maheshwara. Therefore, I should never forget that I'm doing great service in shaping the lives and the character of thousands of students within the four walls of my classroom. Students come to me with great expectations that they will learn something from me. My duty is not only to teach them the syllabus but also to help them build their character. Students who come out of this educational institution with integrity and moral character alone, can make this nation great. It is my responsibility and please to help them achieve that. I will be doing immense service to my country's youth.

“Whatever a great man does, another person does the very same thing; whichever benchmark he sets, the world follows it!” I believe that my students can take inspiration from my life. Teaching without practicing will not produce any favorable outcomes. As modern students are very intelligent, they will observe my life and character. They won't care about our society if they don't see my practice the principles that I teach them. If we sincerely love our students and are really interested in their welfare, they will certainly follow in our footsteps. We must develop infinite patience and forbearance.

In my view focusing on the strengths of the students rather than highlighting their mistakes can be a helpful step in building their confidence. They will grow as independent individuals if we encourage them and be kind, they definitely will show improvement. Giving them positive inputs from time to time will result in helping them in being independent. In poetry, literature and language we must emphasize or highlight the mistakes made by people in order to make the students learn in a better and different way. The teacher can be a friend, philosopher and guide and build a strong relation for life which will help them open up and discuss any issues at any point of time in life. We as teachers must be approachable and must try to the best of our abilities to solve their problems. With mutual respect this strong relation between the student and teacher will blossom. Once they are on the correct path they will grow as individuals with good character, ethics and values. The sense of gratefulness will be there towards the teacher thereby giving the teacher a sense of satisfaction in contributing towards building a happy and peaceful nation.

-DR. MANGAL SINGH

Dear Reader,

For over a century, we have listened to the body's electrical secrets, turning invisible rhythms into life-saving data. That conversation changed forever in 1958 with the first implantable pacemaker—the dawn of a **true symbiosis** between human and machine. For the first time, an electronic device was sealed within the body to actively sustain life. Yet, it was still a one-way street. Until now.

Today, that conversation is becoming a true dialogue. We are beginning to speak back, not with simple pulses, but in a rich language of data, sensors, and intelligent feedback.

Welcome to the frontier where the living cell and the silicon chip don't just communicate—they converge. The promise is to shift medicine from being reactive to predictive, offering care as unique as the individual it serves.

Inside, we explore the technology and the pioneers building this new reality. This is the next chapter in human health, and it's happening now. We invite you to join us.

Some articles in this magazine have been refined with the assistance of AI-based language tools for clarity and readability. The ideas, data and opinions remain solely those of the respective authors and have been reviewed by the editorial team.

Sincerely,
The Editors

LOW POWER DESIGN TECHNIQUES FOR EDGE AI DEVICES

With the progressive increase in the demand of AI, industries are now focused on building efficient, reliable hardware which is more than ever capable of handling and running AI's faster and easier, with so many people incorporating AI into their everyday requirements, AI has become more mainstream than it ever was. With different models being launched in the market, AI based chip companies are spending massive amounts of money to build such kind of hardware that can run AI smoothly and optimize smart models better, thus calling out the need for edge AI devices, but before we talk about edge AI devices, we need to understand what edge AI is.

Edge AI is the deployment of AI applications in devices throughout the physical world. It's called "edge AI" because the AI computation is done near the user at the edge of the network, close to where the data is located, rather than centrally in a cloud computing facility or private data center. Since the internet has global reach, the edge of the network can connote any location. It can be a retail store, factory, hospital or devices all around us, like traffic lights, autonomous machines and phones.

Benefits of edge AI include AI being more powerful and flexible, being able to provide real time insights, and by bringing processing power closer to the edge, applications need less internet bandwidth, which greatly reduces networking costs.

Decentralization and offline capabilities make edge AI more robust since internet access is not required for processing data, which improves the availability and reliability for production grade AI.

Since AI is no longer limited to cloud data centers or high-performance machines; it's being pushed to the edge in the form of mobile devices, smart cameras, industrial sensors, wearables, and other consumer platforms, which are designed to be "always-on," listening, monitoring, or analyzing without pause. That always-on activity drains energy, and most edge devices are battery-powered or operate in environments where power is limited.

To mitigate this challenge, engineers have turned towards low-power designs, which have become the make-or-break factor for bringing edge AI to real-world deployment. Many engineers feel that designing for low power begins at the hardware design level. General-purpose CPUs aren't efficient enough for continuous AI workloads, which is why dedicated accelerators and domain-specific chips have become common. The aim is to maximize processing efficiency per watt, rather than increasing raw performance, thus putting power management techniques into the picture

Here are some low power techniques for edge AI devices:

1. Quantization

Models are typically trained using 32-bit floating point representation. The process of quantization minimizes power consumption by decreasing the precision of neural network parameters (including weights and activations) through conversion to 16-bit floats or, more aggressively, to 8-bit integers. This reduction can decrease the memory footprint by as much as 75%. Additionally, this optimization greatly lowers bandwidth demands and computational power, enabling intricate AI models to operate on devices with limited resources such as wearables, IoT sensors, and smart cameras.

2. Pruning

Pruning methodically eliminates components of a neural network that contribute minimally to accuracy. Unstructured pruning diminishes individual weights, resulting in small and dispersed networks that excel on hardware optimized for scattered computations. Structured pruning takes a more assertive approach by eliminating entire neurons or channels, leading to smaller, denser models that operate more swiftly on conventional processors. When executed correctly, pruning significantly reduces both size and inference time.

3. Knowledge Distillation

Knowledge Distillation draws inspiration from the educational process. A large, advanced 'teacher' model imparts its acquired knowledge to a smaller 'student' model. Although the student is less complex, it is well-trained and can attain comparable accuracy while occupying a fraction of the space and consuming less power. This method has become essential for deploying machine learning models on edge devices, particularly in scenarios where accuracy is critical, such as in AI and ML applications within medical devices.

Tiny ML – Running AI on Microcontrollers

Tiny ML (Machine Learning) refers to a crucial component of machine learning that majorly concentrates on the implementation of models to the microcontrollers and other devices which consume less power and are energy efficient. In more simpler words , It can be described as executing small AI models on low energy devices without using internet. It helps to bring artificial intelligence (AI) on the edge of well-established network system that also helps in much less real time delay and power-efficient inference directly on the device without actually depending on the cloud connectivity. In contrast to wider Embedded AI that includes robust edge servers and IoT devices, TinyML focuses on devices at the smallest end of the scale, typically operating within milliwatt power limits.

Professionals in this field focus mainly on enhancing algorithms and models to sustain performance while reducing power usage and size, allowing smart functionalities in the smallest devices and sensors. TinyML, which stands for "machine learning-aware architectures, frameworks, techniques, tools, and approaches," can be thought of as the combination of three main parts that can do on-device analytics for a variety of sensing modalities. The three main parts are stated as Software, Hardware & Algorithms. Like any other machine learning process, TinyML begins by looking at data and creating and training models on desktop and/or cloud-based software. Depending on the hardware and needs, software that runs TinyML models on edge devices can range from simple implementations to RTOS to Embedded Linux. The hardware can include IoT devices with or without accelerators that use in-memory, analog, and neuromorphic computing to help students learn better. The TinyML system's algorithms should be new so that edge devices with limited resources can use models that are only a few kilobytes in size.

Hardware Platforms for Applications in Tiny ML :

The particular application requirements, such as processing demands, power consumption limitations, pricing, and the availability of development tools and libraries, will determine the hardware platform to select.

Complex hardware processors like GPUs are essential to machine learning tool sets. There are numerous hardware platforms available now for the creation of AI and ML applications. Additionally, there is an increasing amount of specialized hardware for TinyML applications, such as application-specific integrated circuits (ASICs).

Software Frameworks and Libraries Frequently Utilized for TinyML:

Software frameworks and libraries deliver the essential resources that allow for the training, deployment, and optimization of ML models for edge devices. There are several software frameworks available that make it easy to implement TinyML models, either by providing pre-trained models, data processing capabilities, or optimization mechanisms.

Algorithms used for lightweight TinyML:

Classic machine learning algorithms are time-consuming and consume a lot of resources like memory and CPUs/GPUs. In contrast, TinyML algorithms consume very little memory and power since they were created specifically to work in tiny environments such as microcontrollers.

Benefits and limitations of the usage of tiny ml on microcontrollers:

TinyML is a really exciting development in artificial intelligence. It lets us run AI models right on small, simple devices, like the tiny chips we find in many electronic devices, that don't have a lot of power or memory. The big upside to this is that tasks are carried out immediately, there's less waiting around, your personal data stays safer, and the whole system becomes more reliable and consistent because it doesn't constantly need to connect to online services.

Thanks to EdgeAI and TinyML, these devices can make smart decisions by themselves, without needing a constant internet connection. This makes them super useful for settings that are far-flung or don't have many resources. And a huge bonus is that because they can work offline, concerns about keeping your data private and secure really start to fade. TinyML has some advantages to it, but it also has some problems. One big problem with TinyML is that these systems do not have a lot of power to compute things so you cannot use big or complicated AI models on them. Because of this you often have to make a choice between how correct your TinyML model's how well it uses its power. Also getting these TinyML models to work properly on devices can be very hard and can take a long time. It really needs people who're specialists in machine learning and who understand how these small systems work. Finally it is still very difficult to make sure these TinyML models always work correctly and are strong once they are being used in the world especially in places where things can change fast or, without warning. TinyML models have to be reliable and robust. This is hard to do with TinyML.

THREE CHIPS, ONE AI REVOLUTION

~ Apoorba Chatterjee

Your Phone, your laptop, the data centres and network hubs – they're all running Artificial Intelligence on a entirely different hardware. Here is what's actually inside each in of them.

Every time you proceed to unlock your phone with your face id, ask an AI chatbot something, or somehow always get a eerily accurate recommendation on YouTube or any other mean of browsing - a specialised chip made that happen in milliseconds technically in a blink of an eye but it isn't any regular processor. A purpose-built AI chip.

The CPU in your laptop is great at juggling and completely managing lots of different tasks - browsing, running

VS Code, letting you use the best of Arduino IDE, playing music simultaneously.

But Artificial Intelligence works way differently. "Neural networks" are basically just millions of multiplications and the respective calculations happening at once. The CPU, with its couple of powerful cores built for variety, is like asking one genius to solve a million simple sums. But what you would actually want is a million average calculators working in parallel. And that's the core insight behind the three chips that power modern generation of AI - the GPU (Graphics Processing Unit), the TPU (Tensor Processing Unit), and the NPU (Neural Processing Unit).

GRAPHICS PROCESSING UNIT

The chip that accidentally became AI's backbone GPUs were initially built to render video games, to push millions of pixels at once, apply lighting calculations and make the outputs for the same, do it 60 times a second. Well it turns out, the matrix multiplication for neural networks looks almost identical to that of mathematics. In 2012, researchers had began training an image recognition model on GPUs and had absolutely crushed the competition back then, and hence the AI era quietly began. The modern AI GPUs - NVIDIA's H100, used to train models like ChatGPT and used to pack thousands of cores that all run the same field of operation on different data simultaneously making the entirety of the system work together. They are considered to be the workhorses of AI research: flexible enough to handle any model architecture and immensely powerful enough to train billion-parameter networks. Well...the catch? They're power-hungry (700W per card) and very expensive. An H100 (16896 CUDA cores) can cost as much as a car. But when you need to train a large language model, there's still nothing more accessible.

TENSOR PROCESSING UNIT

Google's custom made chip - built for one job and one job only...

Google looked at its GPU setup and had a sudden thought: what if we built a chip that does nothing except the exact maths AI needs? No gaming, no graphics, no general computing but just matrix multiplications, relentlessly, at scale, enough to let consumers use them every second with no delay and utmost speed.

The result is that the TPU is now in its 7th generation. The secret ingredient is a "systolic array". Well imagine a entire grid of tiny calculators passing numbers along somewhat like a bucket brigade, each one doing its small part in respective to how the data flows through. No wasted motion, no idle cores and no thought for letting even one second go to waste. Just pure throughput.

Google uses TPUs to run all of Google Search, Google Photos, Translate, and even its AI Assistant - Gemini. They were never and are not for sale, but you rent them on Google Cloud and that's why TPUs are incredibly efficient for the right job and not flexible enough for anything else to be done.

NEURAL PROCESSING UNIT

The chip already in your pocket - present in every smartphone

Your phone and the phones every other person from every corner of the world almost certainly has an NPU in it right now. Apple calls theirs the Neural Engine whereas Qualcomm calls it the Hexagon and at the same time Samsung has its own. So, every flagship Android and iPhone has one and they are the reason how and why face unlock happens in the dark, in under a second and without draining your battery.

NPUs are designed for inference, basically running a trained AI model, not building one. They are small and run on milliwatts, and live inside the main SoC alongside the CPU and GPU of the phone. They handle the all the AI stuff: voice detection, camera processing, autocomplete, live translation, or even when you ask the weather to your AI Assistant.

The newest ones are surprisingly smoother and hence more capable. The new Snapdragon 8 Elite NPU (45 TOPS) can now run an entire 8-billion-parameter AI model locally on its own without any internet connection and shockingly three years ago that needed a whole server room to do so.

SO WHICH ONE WINS?

None of them, they're a team. The future of AI hardware isn't picking only one chip; it's all three of them working together and helping in each of them to perform their functions.

Your phone's NPU handles the lightweight always-on stuff, then a cloud GPU cluster trains the big models and then comes in Google's TPU pods which serve billions of daily requests with brutal efficiency which shows how each chip plays to its strengths. As an ENTC student, this matters to you directly, whether you end up designing embedded systems, writing firmware, building big apps, or going into VLSI...at the end the AI silicon layer is going to be part of the conversation.

Always. The engineers who understand not just how to use these chips but why they're designed the way they are and why are they a necessity to every person living in this modern era of AI Chips? That's where the interesting problems live.

Epic

YOUR
FUTURE

StartupCon's Fifth Edition - StartupCon 5.0 brought all the pitches, hacks and codes, and big conversations and talks to SIT Pune, and reminded all of us that the next big thing a new entrepreneur might already be sitting in a lecture hall with ideas and creativity somewhere amongst us, all ready to express their ideas. Through all the assignments and all the submissions, a lot of good ideas quietly die, but not because they're bad but because there's no real space or opportunities to take them seriously. That's the gap EPIC, SIT's Entrepreneurship Promotion & Innovation Cell, is trying to fill. Not by promising everyone a way to start a startup or become an entrepreneur, but by making curiosity and problem-solving feel like habits worth building and not making them feel as a task rather a mission to achieve. On March 27th, 2026, EPIC hosted its fifth edition of StartupCon where three events ran through the day - a hackathon, a business pitch competition, a talk show and stalls and exhibitions set outside - each pushing students in a slightly different direction and their area of interest. Let's have a look at what each one looked like.

With complete open choices, teams pitched whatever they believed in and what they thought that would become part of the market, both the freedom and the challenge all combined. With no given - specific problem statement to lean on, the idea itself had to carry the room the creativity and the innovation to create income. Teams of three prepared full decks and stood in front of a panel to make their case, the best pitches weren't just creative they were convincing and, the ones that stumbled and didn't quite make the way probably learned more than the ones that sailed through and got the opportunity to express and understand at the same time.

Pune Symbi Hackothan

3 hours. All Real problems, no shortcuts.

This hackathon wasn't a generic "build an app" prompt here all the participating teams tackled Pune-specific problem statements and real civic issues that actually needed solving throughout all the city. With a tight 3-hour window of 11 AM to 2 PM and teams of four with one female member compulsory, the pressure was the point, during the duration of the Hackathon teams presented to a jury and rested their solutions to the problems they had sought to fix by the use of Tech. It was the kind of format which separates people who can talk about ideas and point out problems from people who can actually create a solution to them and search out more problems to fix and do the needful using the execution of codes.

The Mega Talk Show

Real Founders. Real Stories. Real Talk.

Speakers and Founder from the innovation and entrepreneurship world came in to talk not in the motivational poster way but with honesty with experience and to explain the part they had understood and what, how and which way things happen. These sessions have a tendency to reframe how students think about career paths the ability to take risks, and what "success" actually looks like when you're building something from scratch entirely on your own. If StartupCon had a heartbeat the real motivation, the talk show was it.

Stalls And Exhibition

As every great idea can't just fit right into a pitch deck or a hackathon. The exhibition gave students space to showcase innovations designed for actual revenue generation the prototypes, products, and concepts they had prepared from their own hands and thoughts and the way they had made it successful and had moved beyond the "what if" stage. Walking through the stalls and exhibition felt like a preview of things that might actually exist in the market someday and are ready to come through, and some of the most interesting gossips related to Tech and conversations of the day happened here right between the stalls.

PROTECH 2026

Symbiosis Institute of Technology was the organizer of the technical project competition, Protech 2026. This event gave students from different colleges a chance to present their ideas. The event's main objective was to help give students real-life experiences using what they learnt, helping them apply their knowledge into building practical work. The event was technically backed by the IEEE Maharashtra Section, which helped increase its reach and credibility, allowing students from across Maharashtra and nearby states to participate in this event.

IEEE Maharashtra Section

Students being from different colleges made this event more competitive and diverse. This stressed on the significance of collaboration among both educational institutes and professional organizations in order to provide students with more exposure and experiences.

In total, 155 teams consisting of 553 students participated in the competition. All teams had different-projects related to a particular area such as electronics, software or sustainable solution. The majority of projects offered practical solutions and were based on real problems that exist in today's world. From simple to advanced projects, it helped students cast their technical knowledge and skills onto their projects.

The projects involved more than just creativity, the evaluation looked at whether the project could actually work in real life. Students had to think about feasibility, scalability, and impact.

The event also had Dr. Anil Kumar Gupta from C-DAC Pune as the Chief Guest. He spoke about the importance of staying updated, working consistently, and being open to learning new things. Apart from the competition, the event also encouraged students to network and interact with each other. It gave them a chance to know what others were working on, exchange ideas, and learn new approaches to solving and overcoming problems. It helped them build confidence and grasp command on their communication skills.

The organizing team played a big role in making the event successful. They smoothly handled and managed a large pool of participants. From registrations to final presentations, the process was well organized, and made the overall experience worth it for everyone present.

In conclusion, the event made sure students had a valuable experience, from presenting their work to knowing and learning about different projects that were showcased. With guidance from people like Dr. Anil Kumar Gupta, it encouraged students to keep working on making better and practical solutions for the real world problems.

Student Development Program

The program laid a strong foundation by bridging software proficiency with hardware integration. Students across both Division A and Division B had the privilege of working with "Data Structures using C++" with an industry expert from Seed Infotech, a crucial session facilitated by Dr. Snehal Bhosale and Dr. Jayshree Pande. Understanding that the future of electronics is intrinsically linked to the internet, the schedule dedicated significant time to the Internet of Things (IoT). Through shifting batches, students rotated between the BEST Centre's Sensors and IIoT Lab which was guided by Dr. Kunal Shejul and Prof. Sushma Parihar and the Embedded Lab, where Dr. Akshay Bhosale led a practical, hands-on module on "Implementing Cloud Interfaces for IoT" where he conducted a hands-on session on "Interfacing MQTT with ESP32/ESP8266."

The Department of Electronics and Telecommunication at Symbiosis Institute of Technology, Pune, started off the even term of 2025 - 2026 with a highly engaging Student Development Program (SDP). It was held from 05th January 2026 to 09th January 2026 as the week-long initiative was designed and curated for the Second-Year (SY) E&TC 2024-28 batch. The SDP was designed to take students beyond the traditional classroom setting, offering a hands-on the latest industry trends, core engineering concepts, and cutting-edge exploration of technology.

Recognizing the rapid evolution of artificial intelligence and machine learning, the department ensured the SDP integrated several forward-looking workshops. A major draw was the immersive "Computer Vision Demo cum Workshop" conducted by Copper Cloud, with Dr. Shilpa Hudnurkar and Dr. Shripad Deshpande present to guide the learners. To help the students keep pace with modern AI capabilities, Dr. Aditya Jain delivered a highly engaging session on "Prompt Engineering." Additionally, the cohort explored data visualization through an "Exploratory Data Analysis" demo by Dr. Snehal Bhosale and participated in a dedicated "Image Processing Workshop" which was led by Dr. Sankit Kassa, ensuring they are well-equipped to handle modern data-centric challenges.

True to the core spirit of E&TC, the fundamental domains of electronics and communication were heavily spotlighted throughout the week. A standout moment for many was the comprehensive three-hour session on "Programming FPGA using MATLAB," which was delivered by an expert from MathWorks with Dr. Chandan Choubey in attendance.

The hardware deep-dive continued with insightful talks on "Semiconductors and VLSI," featuring Dr. Mousumi alongside an industry expert. On the communication front, Dr. Priyanka simplified the fundamentals of "How Computers Communicate," while Dr. Mangal Singh offered a glimpse into "Next Gen Communication Tech."

The E&TC Student Development Program of 2026 was a great success, closing the gap between theoretical knowledge and practical, industry-ready skills. With mandatory assignment completions wrapping up the week, the students didn't just absorb (or) rote learn the information but they actively applied it.

One of the most interactive experiences of the week was the "DIY Antenna" building session led by the 3rd year student, Mr. Sundar and attended by Dr. Anurag Mahajan, which allowed students to build communication tools from scratch using Arduino and GSM modules. The system-level engineering perspective was perfectly rounded out by Dr. Mrunal Bachute's introduction to "Model-Based Design."

The E&TC Student Development Program of 2026 was a great success, closing the gap between theoretical knowledge and practical, industry-ready skills. With mandatory assignment completions wrapping up the week, the students didn't just absorb (or) rote learn the information but they actively applied it.

Protathlitis 2026

PROTATHLITIS 2026, the annual sports festival at Symbiosis Institute of Technology, Pune, united the students in a sporting competition. This offered the participants the chance to play and showcase their talents in their choice of sport. Protathlitis made it possible for students to come and play as representatives of their branches in a competitive atmosphere.

The sports festival featured twenty-one sports in total within a period of five days. Basketball, volleyball, table tennis, badminton, pickleball, dodgeball, throwball, handball and eight-ball pool games were some of the sports involved. The list offered diversity of sports to cater to different talents. Participation rules required branches to be selective in choosing events, with Mechanical and Civil/RNA allowed to participate in up to five sports each, while CSE, AIML, and ENTC could participate in up to four sports each. This added a level of planning in team selection and event participation.

ENTC performed strongly across multiple events, securing wins against several branches. In basketball, they defeated teams from Mechanical, AIML, and Civil/RNA. In pickleball, they won matches against Mechanical and CSE teams and secured the top two ranks, including wins within ENTC teams.

They also performed well in 8-ball pool, winning against CSE and Civil/RNA teams to secure top positions. In volleyball, ENTC teams achieved ranking positions with wins over Civil/RNA and CSE. Additionally, they won in dodgeball against AIML and in throwball against Civil/RNA. Their performances continued to be steady, whether in team events or individual events.

Also participating in the sports were other branches such as Mechanical, Civil/RNA, CSE, and AIML. There were some close contests, with consistency in team performances and continued participation in all the events held during the fest.

Scheduling and coordinating of various events went on smoothly, thereby making the matches to take place as scheduled without disturbance.

PROTATHLITIS 2026 stressed participation and competition. It served as an important event in the campus calendar, bringing together students from different branches through sports.

FACULTY ACHIEVEMENTS

1. Dr. Prasad Kantipudi honored with the Outstanding Volunteer Award from the IEEE Bombay Section (5 months ago).
2. Our distinguished E&TC faculty Dr. Sumit Kumar and Dr. Suman Lata Tripathi have been featured in Stanford University's Top 2% Scientists List 2025.
3. Our faculty Dr. Mangal Singh presented a white paper with the Bharat 6G Alliance on the topic: "Powering the Next Gen Telecom: Towards Energy Efficiency in 6G Macro and Small Cell Deployments" at the Indian Mobile Congress (IMC 2025) held at Yashobhoomi, New Delhi on 9–10 October 2025 — a premier platform showcasing the future of connectivity and innovation in telecommunications.

STUDENT ACHIEVEMENTS

1. Sameer Yasin- a second year student was being appointed as the ambassador for India to the International Youth Council on gender equality(IYCGE).
2. Third year students Arya Dhole, Alok Chawat, Aditya Sthawarmath, Aryman Pathak & Saaj Mulik were being selected for the GIP Program 2025.
3. Second year students of Department of Electronics and Telecommunication had the opportunity to visit Otter Controls India Pvt. Ltd. as part of their industry exposure program accompanied by Dr. Chandan Kumar Choubey, Mrs. Arati Mulye, Dr. Kunal Shejul and Mr. Atul More.
4. Sejal Chauhan, a final year student, attended Summer School Program on “AI and Space Sciences” at RUDN University Moscow for two weeks.

5. Anushka Sinha, our final year student, got selected as one of the top ComSoc Student Ambassadors by IEEE USA. Also was awarded a travel grant of USD 800 to attend the prestigious IEEE GLOBECOM 2025 conference held in Taipei.
